

# METHOD AND SYSTEM FOR REMOTELY CONFIGURING AND MONITORING A COMMUNICATION DEVICE

## TECHNICAL FIELD

5           The present invention relates generally to computer network security, and more particularly relates to methods and systems for remotely monitoring the security status of a computer network and remotely configuring communication devices connected to a computer network.

## 10   BACKGROUND OF THE INVENTION

          The rapid increase in the number of burglaries and trespasses has fueled a growing demand for adequate protection against break-ins. Because traditional locks and deadbolts can easily be circumvented, they are largely ineffective against determined burglars and vandals. Remotely monitored security systems typically provide intrusion  
15   protection by constantly monitoring the security status of a property. In a remotely monitored security system, sensors are strategically placed throughout the home or business to detect potential break-ins. If the sensors detect a breach of entry, or movement within the premises, the security system independently transmits an alert to a remote monitoring center. Security personnel located at the remote monitoring center  
20   may then respond with appropriate action, such as notifying individuals listed on an emergency contact list or dispatching the police or fire department. This type of constantly monitored security system offers a great deal of security and peace of mind to a property owner with minimal owner involvement.

          Similarly, computer network owners would appreciate the peace of mind  
25   offered by security systems that remotely monitor their networks for "break-ins." Like the property owner who suffers from break-ins by burglars and vandals, computer network owners experience similar types of "break-ins" by computer trespassers known as "hackers." As global computer networks such as the Internet and its underlying technologies have become increasingly familiar, hackers have acquired unprecedented

opportunities to gain unauthorized access to data, misappropriate sensitive material, destroy or corrupt important files, make unauthorized use of computer resources, interfere with the intended use of computer resources, etc. As experience has shown, the realm of cyberspace—like the realm of real property—has its share of criminals, resulting in a similar demand for adequate protection against “break-ins.”

Traditionally, network owners have utilized firewalls to shield their data and resources from the potential ravages of hackers. In essence, a “firewall” is an electronic device or programmed computer system that functions to regulate the flow of data between two networks. All communications that flow between the networks in either direction must pass through the firewall; otherwise, unwanted non-complying communications may circumvent security. A firewall, which is typically located at a network gateway server, selectively permits the communications to pass from one network to the other. Thus, a firewall acts as a single point of entry to a network where all traffic may be audited, authorized, and authenticated.

Traditional firewalls, however, suffer from serious drawbacks. For example, they generally require extensive monitoring by a skilled individual. That individual must determine whether communications that have failed firewall authentication are attacks upon the network or merely false alarms. In most situations, skilled support personnel must be on-site to perform these tasks. Moreover, the support personnel must analyze each potential attack to determine whether the current firewall protection is adequate or whether it requires fine-tuning. Such determinations can be difficult even for trained technicians. Untrained individuals and small businesses often cannot perform these tasks themselves, and also may not be able to afford the expense of hiring trained on-site personnel.

Another drawback of traditional network firewalls is that many firewalls are expensive and require extensive technical resources for setup and configuration. While larger organizations often have management information systems (MIS) personnel dedicated to installing and configuring the organization’s firewalls and other network

equipment, smaller organizations and individuals may be unable to perform such tasks. Configuring a firewall can often be a daunting task, even for a trained technician. Despite these drawbacks and the increased occurrence of computer network break-ins, prior to the present invention the peace of mind offered by remotely monitored security systems in the real property world does not exist for computer network owners.

Therefore, in light of these problems, there is a need for methods and systems for remotely monitoring communication devices, such as firewalls, for security threats or breaches with little or no end user involvement. There is a further need for methods and systems that can respond to potential security breaches at the communication device without end user intervention. There is an additional need for the ability to remotely configure such communication devices to make them operative, again with little or no end user involvement.

#### SUMMARY OF THE INVENTION

The present invention solves the problems described above by providing methods and systems for remotely configuring and monitoring a communication device, for example a firewall, an intrusion detection device, or similar Internet appliance. According to another aspect of the invention, a communication device such as a firewall can be configured for operation from a remote location, with virtually no end user participation. In addition, the present invention permits rapid response to potential security breaches received at the communication device, without the need for end user intervention.

Generally described, the present invention provides methods for protecting a computer network through a communication device that is capable of determining whether a communication entering the communication device poses a potential security risk to the network or devices on the network. If the communication device determines that such a communication has been received, the device transmits an

alert signal to a remote monitoring center. The remote monitoring center then evaluates the alert and determines how to handle the communication.

More specifically described, a communication device compares incoming communications to entries on a list of communication types established as known security risks. If the incoming communication corresponds to one of the known security risks, the communication device classifies the communication as either a high security risk or low security risk. The reader should appreciate, however, that additional classes of risk may also be included, such as a medium security class. If the communication is found to be a security risk, the communication device transmits an alert signal to a remote monitoring center. Based upon the immediacy of the threat that the communication poses to the network, the communication device takes an appropriate action, for example terminating the communication, prior to contacting the remote monitoring center. In addition, the communication device may also determine and transmit the type of communication causing the alert to the remote monitoring center for analysis and handling.

Upon receiving an alert signal, the remote monitoring center assigns a priority to the alert signal based upon an end user's predetermined stored preferences and the type of communication that caused the alert signal. Based upon that assigned priority, the remote monitoring center then forwards the prioritized alert signal to a computer or human monitoring agent, or may take other appropriate action. The monitoring agent may then analyze the communication and take appropriate action, contact the end user of the communication device with an appropriate resolution, or take other appropriate action.

According to another aspect of the present invention, a communication device, such as a network firewall, an intrusion detection apparatus, or other similar network appliance, may be remotely configured for operation. According to these aspects of the invention, the communication device first determines its own address on a computer network. The communication device then transmits a wake-up signal to a

remote computer, the wake-up signal comprising the determined network address and its unique identification number, which distinguishes that communication device from other devices. The remote computer receives the wake-up signal and configures the communication device by transmitting predetermined configuration information to the device at the previously transmitted network address. The predetermined configuration information is then loaded into the communication device so as to make the device operate in accordance with the configuration information.

According to another aspect of the invention, a user may access a world-wide-web ("WWW" or "web") site maintained at a remote computer and make a request to initiate a remote configuration of the user's communication device. The user provides a unique identification number assigned to the user's communication device and selects a group of configuration options for that device. In response to receiving the unique identification number and request to configure, the remote computer compares that unique identification number with a comprehensive list of recorded valid identification numbers. If a match is found, the remote computer transmits configuration information to the communication device, which is located at the network address associated with the unique identification number previously provided by the user.

According to yet another aspect of the invention, a communication device such as a firewall or other network device can be maintained in an up-to-date status by receiving updated software from a remote computer system, automatically and without user intervention. In accordance with this aspect of the invention, a communication device determines its network address on power-up. The communication device may also at that time activate basic firewall intrusion detection policies to ensure a base level of network security. The communication device then transmits, via an encrypted network channel, communication device status information via a "wake-up" signal, to a remote computer. The wake-up signal comprises the communication device's network address, unique identification number, and status information regarding the device's operational status.

The remote computer receives that wake-up signal and records the information in a database. Based upon the received status information, the remote computer then determines whether the communication device requires a software update. If the device requires such a software update, the remote computer queues any necessary software patches for later download to the communication device.

The remote computer retains the queued software patches until it receives a request to configure the communication device. The request to configure can be received as a request provided by a user from his or her computer system via the Internet, automatically at predetermined intervals, or as a request provided by a technician or security personnel. Predetermined configuration information, which may include these queued software patches, is transmitted to the communication device in response to receiving that request to configure. Upon receiving the request to configure, the remote computer transmits the configuration information to the communication device via an encrypted channel. The configuration information may include the correct time, activation codes, and any necessary software patches, such as the queued software patches described above.

The communication device receives and applies the configuration information and transmits a configuration complete signal to the remote computer. In response to receiving the configuration complete signal, the remote computer records an indication of a successful configuration in a database, and may perform a vulnerability analysis on the communication device. This analysis determines whether the communication device has been configured properly. If the communication device passes the vulnerability analysis, a notice is sent to a user of the communication device (for example, by posting information at a user-accessible WWW site) that the communication device is properly configured and active. However, if the communication device fails the vulnerability analysis, the user may receive a request to modify the device's configuration information.

In this manner, the present invention advantageously provides various methods and systems for monitoring and configuring a communication device. That the present invention improves over the drawbacks of the prior art and accomplishes the objects of the invention will become apparent from the detailed description of the illustrative embodiments to follow.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an illustrative operating environment for implementing aspects of the present invention.

FIG. 2 is a block diagram of a communication device for implementing aspects of the present invention.

FIG. 3 is a diagram showing a WWW page for remotely configuring a communication device.

FIG. 4, consisting of FIGS. 4A and 4B, illustrates WWW pages for configuring security options for a communication device.

FIG. 5 is a flow diagram showing an illustrative method for initiating a remotely configurable and monitorable communication device.

FIG. 6 is a flow diagram showing an illustrative method for remotely configuring and monitoring a communication device.

FIG. 7 is a flow diagram showing an illustrative method for transmitting an initiation code sequence from a communication device to a remote computer.

FIG. 8 is a flow diagram showing an illustrative method for remotely monitoring a communication device.

FIG. 9 is a list exemplary attack signatures as utilized in the present invention.

FIG. 10 is a flow diagram showing an illustrative method for determining an attack and transmitting an alert signal.

FIG. 11 is a flow diagram showing an illustrative method for receiving an alert signal and resolving an attack.

#### DETAILED DESCRIPTION

5           The present invention is directed toward systems and methods for remotely monitoring and remotely configuring a communication device, such as a network firewall, network security device, or other computer network communication device. Aspects of the present invention may be embodied in a communication device operating within a distributed or networked computing environment. In an illustrative  
10       embodiment of the present invention, the communication device comprises a remotely configurable and monitorable firewall intrusion detection appliance. As described above, a firewall protects the resources of a private network from outside communications received from other networks. For instance, an organization utilizing a network through which users may gain access to the entire Internet may install a firewall to prevent  
15       outsiders from accessing its own private resources.

          Although illustrative embodiments of the present invention will be generally described in the context of a communication device operating as a firewall and having intrusion detection functionality within a network environment, those skilled in the art will recognize that aspects of the present invention may be implemented to remotely  
20       configure and remotely monitor other types of network devices. Accordingly, the term "communication device" as used herein means any type of data communication device that can be connected to a computer network and is operative to transmit and/or receive data communications. Specifically, the term also contemplates devices called network or Internet "appliances", that is, devices that connect to a computer network for the  
25       purposes of gathering (inputting), storing, displaying, processing, and/or providing (outputting) information.

### Illustrative Operating Environment

Referring now to the drawings, in which like numerals represent like elements throughout the several figures, aspects of the present invention and the illustrative operating environment will be described. FIG. 1 and the following discussion is intended to provide a description of a suitable environment in which the methods of the invention may be implemented and of the architecture of a preferred embodiment of the invention as a system.

Aspects of the present invention may be implemented in a distributed computing environment such as the global computer network commonly referred to as the "Internet" **108**. In a distributed computing environment, a user computer such as computer **102** are be connected to one another through Local Area Networks ("LANs"), like LAN **104**, through Wide Area Networks ("WANs"), or through public "backbones" such as the Internet **108**. Using protocols well known to those skilled in the art, such as TCP/IP, computer **102** communicates with other computers whether they are also on LAN **104** or on the Internet **108**. Moreover, computer **102** is operative to transmit and receive files and other information to and from server **105** using additional protocols well known to those skilled in the art, for example, file transfer protocol (ftp), telnet, e-mail, etc. Such networking environments are commonplace in offices, enterprise-wide computer networks, intranets, and the Internet.

Computer **102**, LAN **104**, and server **105** are typically connected to the Internet **108** through a communication device **106** such as gateway, firewall, or other device that communicates data between one or more ports. According to an exemplary embodiment of the present invention, communication device **106** comprises a network firewall intrusion detection appliance that is further described with reference to FIG. 2 below. The firewall and intrusion detection functionality of communication device **106** protects the resources of LAN **104** from potential hackers, such as renegade users of the Internet **108** or unauthorized users of LAN **104**, by monitoring the communications received into the device **106** and determining whether such communications comprise a

security risk. The general operation of the firewall and intrusion detection functionality is described below with reference to FIG. 2.

According to one aspect of the invention, communication device **106** is operative to determine whether a received communication comprises a security risk. For example, in the illustrative embodiment of the invention, a hacker **150** attempting to infiltrate LAN **104** may send LAN **104** an unwanted or "attack" communication, such as a GUEST USER LOGIN request, as represented by dashed arrows **152**. Typically, such communications are sent via the Internet **108**, but those skilled in the art will appreciate that such attacks may be transmitted through other means, such as a WAN or MAN (Metropolitan Area Network).

In accordance with the present invention, communication device **106** intercepts the attack from hacker **150** and transmits an alert signal, as represented by dashed arrows **154**, to a remote monitoring center (RMC) **130**. Again, such communications are usually sent through the Internet **108** but those skilled in the art will appreciate that any distributed network environment may be utilized to connect communication device **106** and RMC **130**. The alert signal is handled by the RMC **130**, as will be described next.

The remote monitoring center (RMC) **130** preferably comprises several components that provide functionality for carrying out various aspects of the invention. The RMC **130** may comprise one or more general-purpose computers running application programs for performing several tasks, as will be described. A front end server computer **110** provides an Internet WWW-accessible front end for users to access features and services of the RMC **130** and issue commands for configuration, check status of their devices and networks, and the like. An RMC controller computer **112** stores configuration and other related information about communication devices and networks serviced by the RMC, and generally controls the operations within the RMC. A monitoring engine computer **114** receives threat communications in the form of alert signals from threatened or attacked communication devices. A database farm **132** houses

a plurality of different databases that store information associated with operations of the RMC and of the various communication devices and networks serviced by the RMC. A customer service center **134** comprising a plurality of remote customer service agents **126a, 126b, ... 126n** handles incoming security threats or attacks on behalf of supported customers.

The following actions are exemplary of the manner in which the RMC **130** handles an alert signal received from a supported communication device **106**. The monitoring engine **114** associated with the RMC **130** receives the alert signal from communication device **106** and forwards the alert, as represented by dashed arrow **156**, to selected one of the plurality of remote agents **126a, 126b, ... 126n**. Monitoring engine **114** preferably also maintains a history of attacks on communication device **106** by recording incoming alert signals in a threat database **124** stored in the database farm.

One or more selected remote agents **126** receives the alert signal and determines an appropriate response to the attack of hacker **150**, such as closing LAN **104** to all outside communication or increasing network security at the user's site. The user of the threatened or attacked communication device **106** is then preferably notified of that response. In an illustrative embodiment of the invention, the user may access the response on a computer, such as computer **102**, via a WWW site maintained by the front end server **110**. For example, the remote agents **126** may transmit the response to a WWW server, such as front end **110**, for posting and access by the user. The user may then access that information through Internet **108** via any WWW browser application program known to those skilled in the art, such as Microsoft Corporation's INTERNET EXPLORER™ or Netscape Corporation's NAVIGATOR™ Internet browser programs. Although the illustrative embodiment provides notification via a WWW site, the reader will appreciate that the user may be contacted in other ways, such as via e-mail, telephone, or pager.

According to another aspect of the present invention, the RMC controller **112** is operative to receive activation and configuration information from communication

device **106**, such as its software release version. The RMC controller **112** also preferably records that received information in one or more of the databases **118**, **120**, **122**, and **124**. In addition, RMC controller **112** may transmit software patches and other update information to communication device **106** upon determining that communication device

5 **106** requires such updates.

In an embodiment of the present invention, front end **110** receives requests for WWW pages communicated via a user's browser and transmits such pages to the user of communication device **106**. The requested WWW pages may comprise menus and other screens with which the user may enter billing, configuration, and

10 activation information to configure and activate his or her communication device **106**.

#### Illustrative Embodiments of The Present Invention

With the above preface on the illustrative operating environment for embodiments of the present invention, the remaining FIGS. 2-11, which illustrate aspects

15 of the preferred embodiment of the present invention, will be described.

Referring now to FIG. 2, aspects of the communication device **106** employed in the present invention will be further described. Communications entering and exiting LAN **104** through communication device **106** proceed via an intrusion detector **160** and a firewall **162**. An RMC communication module **165** is operative to

20 receive a signal or message indicative of an attack from the intrusion detector **160** and create a communication to the RMC **130** for handling. A network address buffer **167** stores a network address for the communication device, derived in the manner as described below.

As will be known to those skilled in the art, firewall **162** implements

25 firewall functionality in the known manner by enforcing general entry and exit rules for LAN **104**. While firewalls and intrusion detection systems utilize similar technology, firewalls are not typically designed to merely look for intrusions. The main purpose of a firewall is to keep undesired traffic off the network. Accordingly, in the disclosed

embodiment the firewall **162** may be of a conventional type, used in the known manner, for shielding the LAN **104** from communications traffic determined by the firewall to be excluded.

In addition to firewall functionality, the preferred communication device

5 **106** implements intrusion detection functionality via intrusion detector **160**, by monitoring the communications received into communication device **106** and determining whether such communications comprise an attack or other security risk. More particularly, intrusion detector **160** inspects the unfiltered communications traveling over a specific network segment for the presence of predetermined attack signatures, by

10 comparing to a list **170** of known attack signatures. Attack signatures are activity patterns indicative of undesirable activity, i.e., evidence that an unauthorized communication has been received. Examples of attacks include Denial of Service (DoS) attacks, unauthorized access attacks, attempts to modify data or kill programs, protocol violations, and repeated access attempts indicating malicious intent. Representative examples of

15 attack signatures are shown in FIG. 9 and will be further described below with reference to that figure. Intrusion detector **160** may also monitor for attacks by users that are authorized to be on LAN **104**. Therefore, any attack or unauthorized activity on the network can be detected and the RMC **130** is automatically notified by an alert signal transmitted by the RMC communications module **165**.

20 The function of intrusion detection is well known to those skilled in the art. Typically, an intrusion detection function is carried out in software, and can be implemented in software, hardware, or firmware. Typically, intrusion detection is carried out by comparing an incoming communication (usually comprising a string of characters embedded within a TCP/IP packet, such characters being provided by another computer

25 or a user of another computer that is requesting services) to a list of known attack signatures stored in an attack signature list **170**. The attack signature list is preferably stored in a rewritable memory within the communication device **106** so that the list can be updated as new attack signatures are identified.

By way of example, the intrusion detector **160** may comprise an intrusion detection software application, such as SNORT, which is publicly available under the GNU General Public License GNU89. This network intrusion detection software can perform content searching/matching to entries in an attack signature list **170** in addition to  
5 being used to detect a variety of other known attacks and probes, such as buffer overflows, stealth port scans, CGI attacks, and SMB probes. Details for the construction and manner of use of SNORT are available from the author, Martin Roesch at roesch@clark.net or from the WWW site, <http://www.clark.net/~roesch/security.html>.

As hackers develop new attacks, the skilled artisan must develop  
10 additional attack signatures identifying these new attacks and store information about these attacks so that intrusion detectors can update their associated attack signature list **170**. Those skilled in the art will understand that attack signatures may be obtained from archived and publicly available lists collected by a worldwide community, such as the SNORT signatures. Once an attack and its corresponding attack signature have been  
15 identified, they are stored internally of the communication device for use by intrusion detectors in a collection or database of attack signatures. An intrusion detector then is operative to utilize the stored collection of attack signatures to monitor computer communications to determine if any of those communications match one of the prestored signatures. Upon detecting an attack, the intrusion detector may then transmit an alert  
20 signal via the RMC communication module **165** to indicate an intrusion has taken place or take other appropriate action. An illustrative method for determining attacks and transmitting alert signals is described below with reference to FIG. 10.

The RMC communication module **165** is further operative to control the loading of updates to the operations of the firewall **162**, intrusion detector **160**, and attack  
25 signature list **170**, by receiving queued software updates, patches, and other communications from the RMC controller **112** (FIG. 1).

Referring now to FIG. 3, a communication device **106** constructed in accordance with the present invention can be configured remotely for operation. FIG. 3

illustrates a screen shot of a user interface **214** of a server-based configuration application program utilized for configuration of users' communication devices, as it would appear on a typical user's computer display screen. In the exemplary embodiment of the invention, the server-based configuration application program is hosted by the front end server **110** (FIG. 1), which stores and retrieves information in the databases **132** for communication device configuration. Details of the server-based configuration application are described in connection with FIG. 6. A user with a communication device to be configured accesses the front end server **110** via a standard Internet browser computer application programs such as Microsoft Corporation's INTERNET EXPLORER™ or Netscape Corporation's NAVIGATOR™ programs.

The user interface **214** is used to access and input information, such as identification and billing information, to and from the server-based configuration application, which can be accessed via the Internet at a particular URL. In the example of FIG. 3, the URL (Uniform Resource Locator, the standard manner for indicating a computer's address on the World Wide Web) of the configuration application is <http://REMOTECENTER.NET>, which appears in the browser address field **201**. The site associated with the URL <http://REMOTECENTER.NET> in the described example is located and administered by the front end server **110**, and provides functionality for receiving and displaying configuration and activation information. The user's browser application program provides functionality for receiving and displaying HTML documents in the manner known to those skilled in the art, and the user interface **214** provides interface features for navigating to and between WWW sites and WWW pages, and for providing information to and retrieving information from server-based programs that operate at such WWW sites. The functionality and operation of WWW sites, WWW browser applications, and user interfaces are well known to those skilled in the art.

In the presently described example, a user of communication device **106** visits the REMOTECENTER.NET WWW site and selects a new unit activation button

204 from a main menu 202 to request a new unit activation WWW page from the front end 110. The front end 110 receives that request and transmits a new unit activation screen or region 212, containing empty unit and billing information fields, to the browser application. The new unit activation screen or region 212 is then displayed to the user via the user interface 214, with a number of fields for receiving the user's inputted information. The user will then be prompted to type in these fields information required for activating a new communication device, for example a unique identification number (UIN) 216 corresponding to the user's communication device 106, the user's billing information: including name, address, telephone number, credit card number, e-mail address, selected password, etc.

After filling in the fields in the new unit activation region 212, the user then submits that information by clicking a submit button 226. The user's browser then transmits the information to the front end server 110 for use by the server-based configuration application program.

Upon submission of the UIN and billing information, the UIN is then verified against a comprehensive list of UINs by the server-based configuration application. This comprehensive list may comprise the UINs previously transmitted (via wake-up signals) from communication devices known to have been sold. If the UIN received at the REMOTECENTER.NET WWW site does not match a UIN in that comprehensive list, the server-based configuration application may transmit an error message to the user, such as "UIN invalid, please reenter UIN." If a match is found, however, the UIN and billing information is then stored in an inactive database 120, as is further described with reference to FIG. 5 below.

Still referring to FIG. 3, after the UIN is verified and the UIN and user billing information is stored in the inactive database 120, the user may then select alternate user interface buttons 206, 208, or 210 in the main menu 202 to obtain additional functionality. As described in more detail below with reference to FIG. 4, a modify configuration button 206 may be utilized to change the security policy of the

protected network, for example LAN 104. "Additional function" user interface buttons 208 and 210 may be selected to gain access to additional features of the REMOTECENTER.NET WWW site, as may be established by the operator of the remote monitoring center.

5           Refer now to FIG. 4 for a discussion of the manner employed in the disclosed embodiment of the invention for setting a user's communication device security policy and advanced options for monitoring the device. FIG. 4, consisting of FIGS. 4A and 4B, are illustrative screen shots of user interface 214 displaying user-selectable configuration options for selecting a security policy for the communication device 106 and LAN 104. A security policy may be defined as the set of decisions that, collectively,  
10           determines an organization's or user's posture toward their computer network security. More precisely, a security policy determines the limits of acceptable behavior within the operation of a network and the response to violations.

          In FIG. 4A, a "set policies" information display area 220 is shown in the  
15           user interface 214, which is displayed in response to the user selecting the modify configuration button 206 of the main menu 202. In an illustrative embodiment of the present invention, the set policies information display area 220 includes three user-selectable radio buttons 222a, 222b, 222c representing three distinct levels of computer network security (i.e., three distinct security policies), respectively, high, medium, and  
20           low. A predetermined level of network security, that is, monitoring for certain predetermined threats and providing certain predetermined responses to such threats, may be established by the user.

          The user may easily configure the security policy for communication device 106 by selecting one of the radio buttons, and then clicking the submit button 224.  
25           As will be described in more detail below with reference to FIG. 11, the user-selected security level is utilized to configure the firewall and intrusion detection features of communication device 106 in accordance with the user's preferences, to carry out predetermined responses to certain predetermined threats. Such configuration options

offer the user a simple means of selecting a complex and comprehensive security policy without extensive knowledge or training on the part of the user. The RMC is operative in response to the selection of one of the selectable security levels to automatically configure the communication device to monitor for certain predetermined threats and to provide certain predetermined responses thereto. For example, a high security level may be a policy that monitors for any type of file transfer protocol (ftp) communication received from any source, and responds to such ftp communication by terminating the communication. On the other hand, a medium security level may be a policy that monitors for ftp communications, disallows certain ftp commands but allows others. Continuing the example, a low security level may be a policy that allows almost all ftp commands except certain high risk ones such as a root login.

If the user desires more specific configuration options, the user may alternatively select an advanced options button **320** to display itemized configuration options. FIG. 4B illustrates an advanced options information display area **325** that is displayed in response to selection of the advanced options button **320**. The advanced options information display area **325** includes advanced user-selectable configuration, monitoring, and response options for the user's communication device. According to an illustrative embodiment of the present invention, the advanced options may comprise a list of known attacks, such as an ARP (address resolution protocol) check, clearing of the audit log, change of audit policy, disabling of audit policy, login attempts to disabled or expired accounts, etc. The information display area **325** contains several exemplary types of communications that can be selected for monitoring; other types of communications that can be monitored will be known to those skilled in the art.

Preferably, the advanced options information display area **325** provides a selectable option or intrusion rule for each listed attack so that the user may configure the communication device **106** to monitor selected types of communications and to establish a security level or policy for each. In addition, the user may preferably choose individualized responses to each detected intrusion. For example, as shown in FIG. 4B

the user may categorize each selected attack as either a high priority, low priority, or ignore event. In accordance with the invention, each distinct priority triggers a different level of response in the communications device **106**. For example, the user may select to terminate all high priority events but merely record or log the low priority events. In this manner, a sophisticated user may customize the security options of communication device **106** not only by selecting the communications which need to be monitored, but also determining the level of response to each attack.

Referring now to FIG. 5, an illustrative method **400** for initiating and testing a communication device will be described. The described method or process is preferably implemented as combination of steps carried out by a user when a new communication device **106** is to be installed and configured, in conjunction with computer program steps carried out by the communication device **106** and computer systems associated with the remote monitoring center **130** in response to communications received from a new communication device upon its installation and activation.

Method **400** begins at step **404**, where the user installs communication device **106** by connecting it to both a live network and a power connection. Step **404** proceeds to step **406**, where the communication device **106** determines the IP (Internet Protocol) address of any associated gateway associated with the user's LAN, for example the gateway server **105** in FIG. 1. As known to those skilled in the art, an IP address comprises a predetermined number in the form of NNN.NNN.NNN.NNN, where N is a decimal number, which identifies the sender or receiver of each packet of information that is sent across a TCP/IP network. The obtained IP address is stored in the network address buffer **167** (FIG. 2) for use in network operations, e.g. when identifying itself to the remote monitoring center with the wake-up signal.

In an embodiment of the invention, communication device **106** may obtain the IP address of the gateway by performing a DHCP (Dynamic Host Configuration Protocol) or BOOTP (Bootstrap Protocol) procedure. Either protocol may be used to automatically obtain an IP address without network user involvement. While DHCP is a

more advanced protocol than BOOTP, both configuration management protocols are commonly used and well known to those skilled in the art. In this manner, the communication device **106** can determine its own network address.

Method **400** continues from step **406** to step **408**, where communication  
5 device **106** activates its basic firewall and intrusion detection policies to start protecting  
the network to which it is connected. The method continues from step **408** to step **410**,  
where the communication device **106** transmits a wake-up signal to the RMC **130** via an  
encrypted communications channel. An encrypted data channel may use any form of  
encryption, such as block cipher encryption, which is well know to those skilled in the art.  
10 According to an embodiment of the invention, the wake-up signal comprises the IP  
address, a MAC (Media Access Control) address (i.e., a hardware device level address),  
the UIN, and a software release version number associated with the communication  
device **106**. In addition, the wake-up signal may also comprise diagnostic variables  
associated with the operations of the communication device **106**, such as power source  
15 voltage, internal temperature of communication device, or other parameter indicative of the  
state of operations of the communication devices.

From step **410**, the method **400** continues to step **412**, where RMC **130**  
receives the wake-up signal and records the information contained in the signal in the  
inactive database **120**. From step **412**, the method continues to step **414**, where RMC  
20 **130** compares the information contained in the wake-up signal with a list of required  
standard operating requirements. For example, in an embodiment of the invention, RMC  
**130** reviews the software version and the diagnostic variables received as part of the  
wake-up signal to determine whether communication device **106** is operating correctly.  
In other words, RMC **130** may utilize that information to determine whether the device  
25 **106** is carrying the latest software version or operating within the correct voltage and  
temperature ranges.

Still referring to FIG. 5, from step **414**, the method **400** continues to  
decision block **416**, where a determination is made as to whether the operational,

requirements have been met. If communication device **106** satisfies the operational requirements, the method continues to step **422**, where basic operation of communication device **106** begins. In an embodiment of the present invention, basic operation may comprise activating full firewall intrusion detection functionality of communication device **106** only without the functionality of remote monitoring via RMC **130**. If, however, communication device **106** fails to meet the operational requirements, then method **400** branches to step **418**.

At step **418**, RMC controller **112** queues any necessary software patches, for example an update to the attack signature list **170** (FIG. 2, FIG. 9) for download to communication device **106**. As will be described in more detail below with reference to FIG. 6, these software patches or updates will be transmitted to the communication device **106** upon the user's selection of the new unit activation button **204** (FIG. 3) while connected to the REMOTECENTER.NET WWW site. Method **400** continues from step **418** to step **422**, where, as described above, communication device **106** initiates basic unmonitored operation. Method **400** then proceeds to step **424**, where it ends.

Referring now to FIG. 6, an exemplary method **500** for remotely configuring and monitoring a communication device is described. The method **500** is carried out in the present invention as a combination of steps taken by a user accessing the REMOTECENTER.NET WWW site and computers associated with the RMC **130**. In particular, the front end server **110** provides the necessary user interface **214** for receiving user input (e.g. FIG. 3), and the RMC controller **112** receives the inputted information from the front end server **110**, utilizes that information in the configuration operations, and stores appropriate information in the databases **132**.

Method **500** begins at step **504**, where the user accesses the REMOTECENTER.NET WWW site and enters the UIN of communication device **106** via a user interface **214** such as described in connection with FIG. 3. The UIN may be provided as a label or printing on the communication device **106** or within documentation provided with the device **106**. Method **500** continues from step **504** to step **506** where

the RMC controller **112** receives the entered UIN via the front end **110**. Method **500** then continues to step **508** where RMC controller **112** verifies the entered UIN by comparing the UIN with a list of valid identification numbers, such as a list of identification numbers previously received from communication devices. This list of  
5 previously received UINs is preferably compiled by receiving and saving UINs transmitted from communication devices to the RMC **130** upon power-up (i.e., UINs received from wake-up signals), and storing the list in the inactive database **120**, as described in connection with FIG. 4.

Method **500** continues from step **508** to decision block **510**, where a  
10 determination is made by the RMC controller **112** whether a UIN provided by the user matches a previously received UIN as stored in the inactive database **120**. If the entered UIN cannot be matched to a valid identification number, method **500** branches to step **511**, where an error message is generated, transmitted to the front end server **110**, and displayed to the user via the user interface **214** to inform the user that the entered UIN is  
15 not valid. Method **500** then returns to step **504**, where the front end **110** waits for the user to reenter a valid UIN.

If at decision block **510** it is determined that the UIN matches a previously received UIN, method **500** continues to step **512**, where the front end **110** displays main menu **202** via the user interface **214** and awaits user input. As previously  
20 described in connection with FIG. 3, the menu **202** preferably comprises options for configuring a new communication device, such as represented by the new unit activation button **204**, or modifying the configuration of a previously configured device, such as represented by the modify configuration button **206**.

In response to the selection of a main menu **202** option, method **500**  
25 proceeds from step **512** to decision block **514**, where a determination is made as to whether the user has selected the new unit activation button **204**. If at step **512**, a determination is made that the user has not selected the new unit activation button **204**, method **500** branches to decision block **532**. If, however, the user has selected the new

unit activation button **204**, then method **500** continues to step **516**.

At step **516**, the user is prompted to provide user billing information, such as name, address, telephone number, credit card number, etc. This billing information is used to charge the user of communication device **106** for the monitoring services described herein. Method **500** then continues from step **516** to step **518**, where RMC controller **112** records and associates this billing information to the existing UIN, corresponding to communication device **106**, that is contained in the inactive database **120**, as described with reference to FIG. 5 above. Method **500** then continues from step **518** to step **520**, where RMC controller **112** transmits any software patches contained in a download queue as well as any necessary activation codes to the communication device **106** by way of the RMC communication module **165**, which is further described below with reference to FIG. 7.

Still referring to FIG. 6, from step **520**, method **500** continues to step **522**, where RMC controller **112** moves the recorded information associated with communication device **106** from the inactive database **120** to an active database **118**. This informs monitoring engine **114** to begin monitoring communication device **106** for incoming alert signals. An illustrative method for remotely monitoring communication device **106** is described below with reference to FIG. 8.

Method **500** continues from step **522** to step **524**, where RMC controller **112** transmits the recorded information to the front end server **110** for communication to the user. As will be understood, the configuration information for communication device **106** is stored in the databases **132**, and in particular the active database **118** and the inactive database **120**, which can be accessed by a user via the REMOTECENTER.NET WWW site in response to entry of appropriate security information such as a user name and password. Therefore, if configuration information for communication device **106** is lost, the configuration information can easily be retrieved through the REMOTECENTER.NET WWW site.

Method **500** continues from step **524** to step **526** where the user is

notified via the browser user interface **214** that the communication device **106** is active and fully monitored based upon a set of standard security options. Method **500** then proceeds to step **528**.

At step **528**, RMC controller **112** collects user input via front end **110** as to whether the user wishes to modify the configuration of communication device **106** from the standard security options. In accordance with an embodiment of the present invention, configuration changes may comprise changing intrusion rules, monitoring policies, response policies, and user access policies concerning unsuitable or inappropriate communications received at communication device **106**. Method **500** then continues from step **528** to decision block **532**.

At decision block **523**, reached either from step **514** or step **528**, a determination is made as to whether the user selected the modify configuration button **206** (FIG. 3). If it is determined that the user has not requested to modify the configuration, method **500** returns to step **512**. If, however, the user has selected to modify the configuration, then method **500** continues to step **534**, where the user is prompted to select configuration changes. As described above with reference to FIG. 4, configuration changes may comprise selecting a certain level of security or identifying specific attacks that should be identified as security risks. After RMC controller **112** receives any entered configuration changes via the front end **110**, method **500** continues to step **536**, where the entered configuration changes are added to a download queue. Method **500** then proceeds from step **536** to step **538**.

Still referring to FIG. 6, at step **538** the configuration changes are transmitted via an encrypted channel and applied to communication device **106**. Method **500** then continues to step **540**, where the monitoring engine **114** performs a vulnerability analysis on communication device **106**. In accordance with an embodiment of the present invention, the vulnerability analysis is conducted by communications from the monitoring engine **114** to the particular communications device **106** via the Internet **108**, and preferably comprises checking the security options to determine whether the user has

deselected important intrusion rules and searching for any open ports on communication device **106**. The reader will appreciate that additional types of security checks may be performed on communication device **106**, such as checking password security, encryption security, and the like.

5 From step **540**, method **500** proceeds to decision block **542** where a determination is made whether communication device **106** has passed the vulnerability analysis. If communication device **106** passes the vulnerability analysis, method **500** returns to step **512**. If, however, communication device **106** fails the vulnerability analysis, then method **500** branches to step **544**, where an error message is displayed to  
10 the user and the user is prompted to modify the configuration of communication device **106**. From step **544** method **500** returns to step **534**, where RMC **130** receives for new configuration changes.

Referring now to FIG. 7, a routine **600** for transmitting an initiation code sequence to a communication device **106** will be described. Routine **600** begins at step  
15 **604** where an encrypted communication channel is opened between the RMC communication module **165** of a the communication device **106** and RMC controller **112**. The operation of encrypted communications is well known to those skilled in the art and will not be described further herein. From step **604**, routine **600** proceeds to step **606**, where, according to an embodiment of the invention, the correct time is transmitted to  
20 communication device **106**. Routine **600** then continues to step **608**.

At step **608**, any necessary software updates are transmitted from the RMC controller **112** to the communication device **106** via the RMC communication module **165**. As described above with reference to FIG. 5, the current software release version of communication device **106** is transmitted to RMC controller **112** via the wake-  
25 up signal. This release version is examined by RMC controller **112** to determine if software updates or patches are necessary. If such patches are necessary those patches are obtained from a download database **122** (FIG. 1) and placed in a download queue. In particular, if any updates to the attack signature list **170** have been created at the RMC, an

updated attack signature list can be download into the communication device ro use in detecting new types of attacks.

At step **608**, the contents of the download queue are transmitted to communication device **106** via the encrypted communications channel. Communication device **106** applies any transmitted software patches to its internal firmware, and routine **600** continues from step **608** to step **610**. The reader should appreciate that multiple software versions may be maintained on communication device **106** in case the newest software version is corrupt or improperly installed. For example, in an embodiment of the present invention, two versions are maintained on the device **106**, wherein the older of the two versions is replaced by the newest update. Thus, the two newest versions of software will always be available.

Still referring to FIG. 7, at step **610** RMC controller **112** transmits activation codes necessary to initiate transmission of alert signals from communication device **106** to monitoring engine **114**. After transmission of the activation codes, routine **600** proceeds to step **610**, where communication device **106** transmits a complete signal via its RMC communication module **165** to RMC controller **112** to inform RMC controller **112** that the initiation code sequence has been correctly received and communication device **106** is active. Routine **600** then returns to step **522** (FIG. 6).

Now referring to FIG. 8, a method **700** for remotely monitoring the operation of communication device **106** will be described. The method **700** in the disclosed exemplary embodiment is preferably carried out as a series of computer program steps taken within the communication device **106**, communications to the RMC **130**, and responses taken within the RMC. It will be understood that the method contemplates a communication device **106** that has been previously activated and configured in accordance with processes described earlier herein, and is on a list of active communication devices remotely monitored by the RMC **130**.

Method **700** begins at step **702**, where an activated and remotely monitored communication device **106** receives a communication, for example from a

hacker **150** (FIG. 1). This communication may constitute a threat or attack to the user's network, or may merely constitute a desired communication. Method **700** continues to step **704**, where the received communication is compared to a list of known attacks and the result of the comparison is provided to a decision block **706**. Preferably, all received communications are analyzed and compared to the list of known attacks. As described above with reference to FIG. 4B, a received communication will generally constitute a security risk if the type of communication received matches a communication type on the predetermined list **170** of communication types deemed to be attacks.

If at decision **706** the received communication matches one of the known types of attacks on the list maintained at the communication device, a "threat event" is deemed to have occurred. The method then branches to step **707**. If at decision **706** the received communication does not match one of the known types of attacks on the list maintained at the communication device, the communication is not deemed threatening and control passes to step **712**, where the communication is routed to its destination.

At decision block **707**, a determination is made as to the priority of the threat event. In particular, the determination is made first whether the threat event further comprises a low priority event. Based upon security options selected by the user, a low priority event comprises a security risk that is deemed not to present a serious threat and therefore does not necessarily require immediate response on the part of the RMC. If the threat event is determined to comprise a low priority event, method **700** continues to step **708**, where a low priority response action is taken. In the disclosed embodiment, a low priority response action entails the transmission of an alert signal to RMC **130** for evaluation. Those skilled in the art will understand that other types of actions may be taken in response to a low priority event, as determined by and at the discretion of the system operator.

If at decision block **707** it is determined that the threat event does not comprise a low priority event, method **700** branches to decision block **710**, where a further determination is made whether the threat event comprises a high priority event.

According to an embodiment of the present invention, a high priority event may comprise a serious threat such as a DoS attack. The goal of a DoS attack is not to steal information, but to disable a device or network so users no longer have access to network resources. For example, "WinNuke," a widely available DoS tool, may be used to remotely crash any unprotected computer running Microsoft Corporation's Windows operating systems. In accordance with the invention, the communication device **106** may be configured to protect LAN **104** from WinNuke and other DoS attacks by providing information indicative of DoS attacks in the list of security risks.

If a determination is made that the threat event does not comprise a high priority event, the remaining or default state is that the user has selected the "ignore" button (FIG. 4B) for the communication, notwithstanding that the event is on the list of known security risks, and the method **700** branches to step **712** where the communication is routed to its intended destination.

After step **712**, where the communication is routed to its intended destination, the method **700** then returns to step **702**, where the communication device **106** continues to receive and analyze communications.

Still referring to FIG. 8, if at decision block **710** the communication is determined to constitute a high priority threat event, and therefore a high security risk, method **700** continues to step **713**, where a high priority event action is taken. In the disclosed embodiment, a high priority event action calls for immediate protective action. Accordingly, the preferred high priority event action includes decision block **714** where a determination is made as to whether the communication comprises such an immediate threat to LAN **104** that it should be immediately terminated. In that case, method **700** branches to step **716**, where communication device **106** terminates the received communication, for example by discarding the TCP/IP packet. Method **700** then proceeds to step **718**.

Those skilled in the art will understand that other responses to a high priority threat event may also be taken, not merely termination of the connection, for

example, by providing a visible threat indicator to the user by generating an error message on a computer associated with the user's LAN **104**, for example computer **102** (FIG. 1), by locally logging communications received from the source of the communication, or by isolating one or more threatened computers from the remainder of the network, etc.

5 Other appropriate responses will occur to those skilled in the art.

If at step **714** a determination is made that the communication should not be terminated, method **700** continues to step **718** without terminating the communication. In an embodiment of the present invention, high priority events includes various types of DoS attacks and will always be terminated. The reader should appreciate, however, that  
10 the user may categorize additional non-DoS attacks as high priority events, which the user may not necessarily consider serious enough to cause immediate termination.

In an embodiment of the present invention, all communications (even if they do not comprise a high or low priority event) may be transmitted and recorded at RMC **130** for subsequent analysis. Furthermore, in the described embodiment both high  
15 priority and low priority events cause the transmission of an alert signal to the RMS **130**. Thus, at step **718**, which can be reached either from step **708** or **714**, communication device **106** transmits an alert signal to monitoring engine **114**. An illustrative method for determining attacks and transmitting alert signals is further described below with reference to FIG. 10.

20 Method **700** continues from step **718** to step **720**, where monitoring engine **114** receives and records the alert signal in a threat database **124**. Method **700** then continues to step **720** where monitoring engine **114** assigns an order preference to the attack based upon the type of received communication and predefined user response policies. From step **720**, method **700** proceeds to step **724**, where monitoring engine **114**  
25 forwards the communication to one of the remote agents **126a-126n** based upon that assigned order. In an embodiment of the present invention, remote agents **126a-126n** may comprise human technicians or software application programs for classifying and handling identified security risks.

Method **700** continues to step **726** where one or more of the remote agents **126a-126n** analyze the received communication and provide a resolution, such as terminating the communication (if not already done), modifying the security options of communication device **106**, and the like. Additionally, the user may be contacted with an appropriate resolution, such as by transmitting instructions to the communication device to cause disconnection of LAN **104** from outside networks. The user can be contacted in various manners, for example, by e-mail, by beeper, by telephone, by a predetermined communication issued to a particular port on the user's computer system, or by other communication means. Method **700** then ends at step **728**. An illustrative method for receiving alerts and resolving attacks is further described below with reference to FIG. 11.

Refer now to FIG. 9 for a discussion of the list **170** of simplified exemplary attack signatures. As described above in connection with FIG. 8, a communication device **106** constructed in accordance with the present invention is operative to store a list **170** of attack signatures, and to compare an incoming communication to entries on the list to determine if a received communication constitutes a threat event and respond accordingly. The list **170** comprises a plurality of entries, preferably arranged in a predetermined sort order to facilitate rapid access by indexing or hashing.

Each exemplary entry on the list **170** comprises a header field **810**, a body field **820**, and a two-bit priority field **826**. The priority field **826** in the disclosed embodiment is 00 = ignore, 01 = low priority, 10 = not assigned (unused), and 11 = high priority. Those skilled in the art will understand that the priority field is set in accordance with user and/or predetermined remote monitoring system preferences, for example by establishing certain predetermined priorities for certain types of signatures via a high, medium, or low set policy (FIG. 4A), or by user setting of priority through the advanced options settings (FIG. 4B).

The header **810** may comprise an IP address **812** and a port number **814**.

The IP address is the destination address of the communication device. Port numbers appear after the IP address and typically indicate a particular type of data communication service, some of which are known to be associated with security attacks, for example, a login host protocol on port 49. As will be known to those skilled in the art, Internet data communication services are provided on a particular port number of a particular server that provides that service, with the port number identifying a type of data communication service. While most Internet data communication services have standard port numbers (e.g., port 21 is for **ftp** (file transfer protocol) services, port 23 is for **telnet** services, port 25 is for **smtp** (e-mail), port 80 is for **http** (hypertext transfer protocol used for the WWW), etc.), services can also occur on non-standard ports. Those skilled in the art will understand that standard port numbers can be obtained by reference to Internet Request for Comments (RFC) 1700, Assigned Numbers, by J. Reynolds, J. Postel, July 1994.

The reader should appreciate that header **810** may comprise additional elements, such as source and destination IP addresses, source and destination ports, fragmented bits and data transfer protocols, etc., which are well known to those skilled in the art.

Attack signatures may further comprise a body **820** comprising a message field **822** and a content field **824**. The message **822** is indicative of the communication's type. For example, an exemplary attack signature **830** for a ROOT login attempt on an FTP server shows a message **833**, "FTP-user-root." The content **834** may comprise the actual character string entered by the source of the communication. For example, attack signature **830** contains a string "user root lodl" (where lodl represents a carriage return), which is the exact sequence of characters that would be entered by a person (such as a hacker) attempting to enter an ftp-capable server and issue commands at the "root level" of access. The root level, as will be known to those skilled in the art, is the highest level of access to a computer's services, which essentially means access to all files and services offered by that computer.

As another example, the attack signature **832** indicates an incoming communication intended for port 23 with a message field of "any" and a data field of "any". This means that any communication received on port 23 having "any" information whatsoever in the message or content fields will be treated in accordance with the assigned priority. In the example given, the attack signature **832** is assigned a high priority (11), indicative that any communication on port 23 should be deemed a serious threat and treated accordingly.

It will now be understood that the list or table **170** comprises a collection of information indicative of various types of attacks or threats on computers that might be issued by unauthorized persons or hackers, that this list is maintained within a communication device **106** constructed to be operative in accordance with the present invention, and that the entries on this list are utilized by a communication device as it carries out the step **704** (FIG. 8) of comparing an incoming communication to entries in the list. It will be further appreciated that this list may be changed from time to time by loading in a new or updated list directly from a device connected to the LAN **104** (FIG. 1), by way of a communication received from the RMC controller **112**, or by other means. In this manner, communication devices may be kept up to date as new security threats are discovered and documented.

Referring now to FIG. 10, an illustrative method **900** for detecting attacks and transmitting alert signals will be described. The method **900** is preferably carried out within a communication device **106**, by intrusion detector **160** in conjunction with RMC communication module **165**.

Method **900** begins at step **902**, where the communication device **106** receives a communication that arrives at intrusion detector **160**. Method **900** continues from step **902** to step **904** where communication device **106** disassembles the communication to ascertain the communication's "header" information, such as the port number.

Method **900** continues from step **904** to step **906**, where the intrusion detector **160** compares the communication's "header" information with entries in the list **170** of attack signatures, and passes to decision block **910**. If the information in the incoming communication does not match an entry in the list **170** (e.g. the port number of the communication), control passes to step **912** and the communication is routed to its intended destination. However, if the information in the incoming communication matches an entry in the list **170**, control passes to step **916** where the communication's body is disassembled. Control then passes to step **918**.

At step **918**, the communication body is compared to the corresponding body portions (message and content) on the list **170** of attack signatures, and control passes to decision **919**. If the communication's body does not match any entries on the list, no action for this type of communication is indicated and control passes to step **912**, where the communication is routed to its intended destination. If the communication's body matches an entry on the list, then control passes to step **920** where the priority for the list entry is examined and determined. Control passes to decision **922**.

At decision **922**, if the entry has a high priority, a high priority action is taken at step **926**. For example, a high priority action may entail terminating the communication locally and sending an alert to the remote monitoring center. At decision **922** if the entry does not have a high priority, control passes to decision **924**. At decision **924** if the entry has a low priority, a low priority action is taken at step **928**. For example, a low priority action may only entail the transmission of an alert to the remote monitoring center without any further local action.

After determining the appropriate actions for high and low priority events at steps 926 and 928, control passes to step 930, where the violated rule is transmitted to the remote monitoring center (RMC) for logging or other appropriate action at the RMC. In the disclosed embodiment, the violated rule constitutes information indicative of the communication received, including port number, message body, message content, and any other information associated with the communication that the RMC may wish to log and inspect. Preferably, the violated rule is transmitted by encapsulating the communication in a TCP/IP packet addressed to the RMC, and transmitting the encapsulated communication via an encrypted channel.

Now referring to FIG. 11, an illustrative method 1000 for receiving alert signals and resolving attacks will be described. Method 1000 is carried out as steps within the RMC 130 in the disclosed embodiment of the invention.

Method 1000 begins at step 1004, where the RMC 130 receives an alert signal from a communication device 106 that has detected a threat or attack as described in connection with FIG. 10. Method 1000 continues from step 1004 to step 1006, where the monitoring engine 114 of RMC 130 records or logs the alert signal in a threat database 124. Based upon provisions of the user's monitoring agreement (i.e., a predetermined arrangement between a user and the operator of the RMC 130) the threat database 124 may comprise multiple databases, such as a high threat database and a low threat database. In an embodiment of the present invention, the alert signal contains priority information indicative of the seriousness of the attack. Based upon this priority information, the communication is stored in the corresponding threat database.

In addition, reception of an alert signal primes the RMC 130 into taking timely and effective action in response to possible attacks. For example, the reception of an alert signal may initiate RMC 130 into obtaining bandwidth, apportioning memory space, and scheduling an available agent 126 to handle the incident. Those skilled in the art will understand that the described two-part method of communicating information

about an attack advantageously sets up the RMC to handle the threat incident expeditiously, by (1) receiving and logging the alert signal automatically, (2) determining the seriousness of the attack, and (3) prioritizing and queuing the most serious threats for handling by one of the remote agents, in an order determined by agent availability and seriousness of the attack.

Method **1000** then continues from step **1006** to step **1008**, where monitoring engine **114** receives the second packet from communication device **106** notifying it of the specific intrusion rule that was violated. Method **1000** proceeds to step **1010**, where monitoring engine **114** assigns an order preference to the attack based upon the assigned priority, rule violated, and predefined user response policies.

In accordance with an illustrative embodiment of the invention, predefined user response policies may depend wholly on the user's preferences. For example, an organization that employs the UNIX operating system on their computers may be concerned about tracking ROOT logins (i.e., login attempts as ROOT) as potential attacks. This would especially be true if that organization restricted ROOT logins to select persons and/or if the organization seldom utilized ROOT logins. On the other hand, a firm that employs Microsoft Corporation's WINDOWS 98™ operating system may be less concerned about ROOT login attempts since ROOT logins are non-functional on those systems.

From step **1008**, method **1000** proceeds to step **1010**, where monitoring engine **114** forwards the communication to one or more of the remote agents **126a-126n** based upon the assigned order.

Method **1000** continues to step **1012** where one or more of the remote agents **126a-126n** analyze the received communication and provide an appropriate resolution, such as terminating the communication and/or modifying the security options of communication device **106**. The reader should appreciate that appropriate resolutions may also comprise low tech responses, such as contacting the intrusion source. Method **1000** then ends at step **1016**.

In view of the foregoing, it will be appreciated that the present invention provides methods and systems for remotely configuring and monitoring a communication device. It should be understood that the foregoing relates only to specific embodiments of the present invention, and that numerous changes may be made therein without departing from the spirit and scope of the invention as defined by the following claims.
